

Block Ingestion Test Document

1. Introduction

This document exercises the Docling block adapter used by the PDF block ingestion pipeline. It contains multiple pages, section headings, body paragraphs, and a short bulleted list so the parser emits typed blocks.

The introduction establishes the purpose of the test fixture and the structure that the layout analysis is expected to recover from the page.

- Headings become heading blocks with a level.
- Paragraphs become paragraph blocks.
- Bounding boxes are normalized to the unit square.

2. Methods

The methods section describes how the fixture was produced and how the adapter converts Docling items into typed ParsedBlock records.

Each block carries a page number, a type, optional text, and an optional bounding box. The shared finalize pass reindexes sequence numbers and computes the section outline from heading levels on every page.

3. Results and Conclusion

Results confirm that page order is monotonic and that every bounding box produced by the adapter lies within the normalized zero to one range.

In conclusion, the fixture provides a compact, deterministic input for the unit tests that guard the parser contract across future changes.
